TYPE 4060 ASYNCHRONOUS MULTIPLEXOR

014-000004-04

The Data General 4060 Asynchronous Multiplexor System enables any Nova-line computer to communicate with and control terminal devices over a variety of communications facilities. The modularity of the 4060 hardware permits simple system expansion, the addition of new features, or the addition of special purpose equipment as the need arises. The 4060 series is supported by software driver package under both RTOS and RDOS.

SECTION 0

INTRODUCTION

The Data General 4060 Asynchronous Multiplexor System enables any Nova-line computer to communicate with and control terminal devices over a variety of communications facilities. A system is configured from a number of essential and optional subsystems which allow the system characteristics to be adjusted to match the anticipated usage . The modularity of the 4060 hardware permits simple system expansion, the addition of new features, or the addition of special purpose equipment as the need arises. Only asynchronous communication is supported by the multiplexor; the types 4015, 4073, and 4074 communication controllers are available for synchronous or bisynchronous communication. The type 4073 and 4074 can be intermixed with the 4060 series, allowing for one software system responding to a single device code.

)

The 4060 multiplexor system is unique in that all circuitry required for the multiplexing function is distributed on interface card subsystems each handling four lines. There is no common control circuitry. Each four-line interface card is self-contained; it includes all the circuitry necessary to receive, transmit, and buffer characters for four lines. From 1 to 16 cards serving 4 to 64 lines operate together as a multiplexing system. Such modularity not only minimizes overhead costs for smaller configurations but also localizes most failures to a small group of lines. A single four-line card is a convenient controller for up to four teletypes or higher speed visual display terminals connected locally.

Complete hardware assembly/disassembly and buffering of characters is provided. The software device handler is interrupted only when a new character must be supplied to or accepted from the multiplexor.

The modularity of the 4060 hardware allows, in groups of four lines:

- a) Several distinct communications line speeds in a single system (up to 9600 baud).
- b) Several transmission codes in a single system (5,6,7, and 8 level with 1, 14, or 2 stop bits).
- c) Easy system expansion from a minimum of four lines to a maximum of 64.
- d) Direct (current loop) connection, modem (data set) interface, or modem control for automatic answer.

- e) Hardware character assembly/disassembly with full character buffering.
- f) Full duplex operation.
- g) Four complete line interfaces on each standard Nova-Line subassembly card.

SECTION 1

OPERATION AND SPECIFICATION - GENERAL

In communicating with the terminal or data set, the multiplexor hardware performs all character assembly and disassembly into the serial bit streams required. Start and stop bits are inserted on transmission and stripped out on reception. Character buffering is provided on both reception and transmission so that the program has a full character time to respond without losing input data or reducing transmission rate.

The multiplexor system is flexible in line capacity, transmission code, and line speed. It can accommodate from four to 64 full duplex lines, in multiples of four, at speeds including 9600 baud. The transmission code structure (character size and number of stop bits) and line speeds are selectable by the user so that an installation can be reconfigured with minimal hardware change. Requirements for spare parts are minimal.

A number of four-line receiver/transmitter cards appear as if they were a single I/O device connected to the computer under a single device code. On reception, an I/O instruction reads words containing the line number in the left half and a character in the right. At the completion of transmission of a character, an I/O instruction reads a similar word containing the line number indicating that a character has been transmitted; the program responds by outputting a word containing the appropriate line number and new character. Multiplexing occurs since the I/O instruction to read a line number/character word and control information always effects only one line on one of the several cards. The choice of which of several cards is made automatically by the hardware in priority order, lower line numbers having the higher priority.

At the maximum data rate of the multiplexor system (64 lines each operating at 9600 baud) over 60,000 characters are each received and transmitted every second. Such a data rate allows only 8 microseconds for processing each character; this is inadequate except for trivial operations. Most configurations, however, do not require asynchronous communications at rates exceeding 1200 baud as this rate is currently a standard for the higher speed asynchronous modems and display terminals. At this lower rate, a more generous amount of processing time is available for each character.

Synchronous communications, using the Data General Type 4015 communications controller which operates through the direct memory access data channel, is more common at speeds of 2400 baud and above for which high performance synchronous modems are available.

Four-line cards physically mounted closer to the processor along the I/O bus have a higher priority in obtaining the • processor's attention. Thus, in a system with mixed baud rates, the higher speed lines should be assigned to lower line numbers.

MODELS

)

1

Each four-line asynchronous receiver/transmitter card is available in several models. The Type 4060 and 4061 each provide interfacing to four 20 milliampere teletypes. Type 4062 and 4063 provide interfacing to four EIA Type lines either for use with local Teletypes Model 37, Bell System 103-type data sets (modems) or equivalent equipped for manual answer or used on a dedicated line, or other terminal devices with the EIA type interface. The transmitter circuitry examines the Clear to Send signal (Circuit CB) and will not begin transmission of a character unless that control signal is true.

The 4060 and 4062 models come equipped with four individual connectors (9-pin for 800/1200/1230, 50-pin paddle board for 1210/1220/820 series processors) for direct connection of terminal devices or for connection to manual answer modems. The 4061 and 4063 models are provided with a connector arrangement which allows use of the 4050 or 4051 junction panel on 800/ 1200/1230 and 4083 on 1210/1220/820 series which is described more fully in the cabling section.

		EIA INTERFA	CE CIRCUITRY

SECTION 2

RTOS/RDOS SOFTWARE DRIVER

In order to provide a 4060 series communication system which requires the minimal amount of user-program involvement, a device handler was programmed and incorporated in both the Real Time Operating System (RTOS), and the Real Time Disc Operating System (RDOS).

Real Time Operating System is a compatible subset of RDOS. In applications not requiring program overlaying or file naming, it is a flexible, modular interface to user programs in either real-time or off-line environments. Multitasking, timer control, and I/O transfers are handled by simple task and system calls to RTOS. Standard Data General peripherals are supported.

Real Time Disc Operating System is a modular, multitask synchronization and communication system. Tasks may exist in the single mode root program or in an overlay. RDOS operates with any Nova-line computer of 12K or larger memory, disc, real time clock, and Teletype.

RDOS is used in both the development and implementation of programs. It includes all the file capabilities normally available on disc operating systems, allowing the user to edit, assemble, execute, debug, compile, load-and-go, save, and delete files. Files are protected using system defined attributes. File directories are maintained on a fixed head disc and disc pack basis, where each disc pack can be removed from the system. Peripherals are treated as files, providing device independence by symbolic name. Files may be in sequential, random (indexed), and contiguous formats.

The I/O facility includes buffered I/O for ease of programming and unbuffered block transfers for real time applications. Error messages generated in real time can be spooled and output off-line. RDOS supports up to eight fixed head discs or magnetic tape drives, and up to four disc pack units, and all standard Data General peripherals.

Provisions are made for the full use of RTOS and RDOS multitasking capability. Under the initial 4060 series handler release, each line on a system must be dedicated to a separate task.

It is assumed that the reader of this document is sufficiently familiar with either/or RTOS-RDOS file structure and user calls. Refer to RTOS Manual 093-000056 and RDOS Manual 093-000075. Only those calls directly associated with the 4060 series handler will be discussed here.

FILENAME DEFINITION

)

)

In RTOS/RDOS each physical input/output device is referred to by some unique filename. In this case, each multiplexed line of the 4060 series corresponds to a filename of the form

QTY: X

where "X" is the multiplexor line number in the range 0 to 63.

OPENING A LINE

Before any reads or writes can occur, a filename or line must be logically connected to a channel number through use of an .OPEN call. The channel number is simply a means by which devices can be referenced in read and write calls without use of a specific file name. This call opens the line for reading or writing. ACO must contain a byte pointer pointing to the file name. ACl contains the "characteristic inhibit" mask. For each of the following bits set in the mask, the corresponding characteristic or function is inhibited:

BIT	MNEMONIC*	FUNCTION
10	DCKEY	Echo each input character during a read line.
7	DCPCK	Check for even parity on read line. Generate even parity on write line.
6	DCLAC	Transmit a line feed after each carriage re- turn during a read line or write line.

*All mnemonics refer to user parameters defined on the RTOS/RDOS user parameter list.

EXAMPLE of User OPEN Sequence:

LDA 0,NMPTR ;GET BYTE POINTER LDA 1, MASK ; INHIBIT MASK .SYSTEM .OPEN 2 ;2 IS CHANNEL NUMBER ERROR RETURN NORMAL RETURN NMPTR: .+1 *2 .TXT*QTY:5* :FOR LINE 5 MASK: DCPCK

; INHIBIT PARITY CHECKS

If the error return were taken, AC2 must be examined for one of the following conditions:

MEANING

0	ERFNO	Illegal channel number.
1	ERFNM	Illegal filename.
12	ERDLE	File does not exit.
21	ERUFT	Attempt to use channel
		already in use.

CLOSING A LINE

MNEMONIC

AC2

AC2

After use, the line must be closed to release the channel assigned to it.

EXAMPLE of Close Sequence:

.SYSTEM .CLOSE 2; Channel 2 ERROR RETURN NORMAL RETURN

If the error return were taken, AC2 must be examined for one of the following conditions:

MEANING

		· · · · · · · · · · · · · · · · · · ·
0 15	ERFNO ERFOP	Illegal channel number. Attempt to reference a channel not in use.

READING AND WRITING DATA

GENERAL INFORMATION

MNEMONIC

In a multitask system such as RDOS, it is possible for the user to do simultaneous reading and writing on one or several 4060 lines through use of the standard input/output calls. The following rules must be noted:

> 1) No input/output buffering is done within the 4060 driver programs. The read or write call specifies the buffer area to be used. Any data received before a read call for the line is made will be lost.

- 2) Control is not returned to the calling task until the read or write is completed, that is, all data have been transmitted.
- 3) Simultaneous reads or writes can be achieved through the creation of a task controlling each line. Simultaneous reading and writing on a given line (full duplex operation) is possible and requires the use of two tasks, one for input and another for output. In full duplex operation, the echo return and line feed insertion features must be inhibited.

READ A LINE)

This command causes an ASCII type line to be read. ACO contains a byte pointer to the starting byte address of the buffer where the data is to be read.

Reading will terminate normally after transmitting either a carriage return, or a form feed to the user. Reading will terminate abnormally after transmission of 132 (decimal) characters without detecting a carriage return or a form feed, upon detection of a parity error, or upon end-of-file (ASCII Sub-Control Z). In all cases, the byte count read will be returned in ACL. If the read is terminated because of a parity error, the character having incorrect parity will be stored (high order bit zero) as the last character read. All characters received will be passed to the user, including NULL's, line feeds, and deletes.

EXAMPLE of Read Sequence:

LDA 0,BPTR .SYSTEM .RDL 2 ;READ CHANNEL 2 ERROR RETURN NORMAL RETURN

BPTR: .+1+2 BUF: .BLK 66.

MNEMONIC

202

. .

If the error return were taken, AC2 must be examined for one of the following possible conditions:

MEANING

<u>ncz</u>	MEHONIC	MEANING
0	ERFNO	Illegal Channel Number.
6	EREOF	End of File.
15	ERFOP	Attempt tc reference a file not opened.
22	ERLLI	Line limit (132 characters) exceeded.
24	ERPAR	Parity Error.
26	ERMEM	Attempt to use illegal memory address.
47	ERSIM	Attempt to read a line already reading.

READ SEQUENTIAL

Sequential mode transmits data exactly as read from the file. ACO must contain a byte pointer to the starting byte address of the buffer where the data is to be read. There is no end of file code or timeout. and parity bits are not checked.

EXAMPLE of Read Sequential Sequence:

LDA	0,BPTR	;GET BYTE POINTER
LDA	l,COUNT	;DATA COUNT
.SYS	TEM	
.RDS	2	; READ CHANNEL 2
ERRO	R RETURN	
NORM	AL RETURN	

If the error return were taken, AC2 must be examined for one of the following possible conditions:

<u>AC2</u>	MNEMONIC	MEANING
0	ERFNO	Illegal channel number.
15	ERFOP	Attempt to reference a file
26	ERMEM	not opened. Attempt to use illegal
47	ERSIM	memory address. Simultaneous reads on same line.

WRITE A LINE SEQUENCE

ACO must contain a byte pointer to the starting byte address of the buffer where the data can be found.

Writing will terminate normally upon writing of a null, a carriage return, or a form feed, and abnormally after transmission of 132 (decimal characters) without detection of a carriage return, a null, or a form feed. In all cases, ACl will contain, upon termination, the number of bytes written from the user area to complete the request.

EXAMPLE of Write a Line Sequence:

LDA	0,BPTR	;GET BYTE POINTER
.SYS	TEM	
.WRL	2	WRITE CHANNEL 2
ERRO	R RETURN	
NORM	AL RETURN	

If an error return were taken, AC2 must be interrogated for one of the following possible conditions:

same line.

Simultaneous writes on

AC2	MNEMONIC	MEANING
0	ERFNO	Illegal channel number.
15	ERFOP	File not open.
22	ERLLI	Line limit exceeded.

ERSIM

47

WRITE SEQUENTIAL SEQUENCE

This command writes data exactly as it is found in the user area. ACO must contain a byte pointer to the starting byte address of the buffer where the data can be found.

EXAMPLE of Write Sequential Sequence:

LDA 0,BPTR ;GET BYTE POINTER LDA 1,COUNT ;GET BYTE COUNT .SYSTEM ;WRITE CHANNEL 2 .WRS 2 ERROR RETURN NORMAL RETURN

If an error return were taken, AC2 must be interrogated for one of the following possible conditions:

AC2 MNEMONIC MEANING

)

0	ERFNO	Illegal channel number.
15	ERFOP	File not open.
47	ERSIM	Simultaneous writes on same
		line.

SECTION 3

PHYSICAL LEVEL PROGRAMMING

A receiver indicator (RI) and a transmit indicator (TI) are associated with each line. The receive indicator is set when a character has been assembled from the serial input stream; it is cleared under program control. The transmit indicator is set whenever the line unit circuitry has accepted a character for transmission and is ready to accept another. I/O reset clears all transmit character - The character just received on the and receive indicators. Since the transmitter indicated line if RI is set: uncircuitry includes double buffering, the transmit indicator is set almost immediately after accepting the first character following a long idle period. At maximum transmission rate, the transmit indicator is set once per character time; it is cleared under program control.

The four line receiver/transmitter cards contain conventional DONE flags for interface to a Nova-line I/O bus. These are logically ORed together to get a system DONE (QTY DONE). To the programmer, QTY DONE appears set if any input lines have completely assembled characters ready for reading by the character - The character to be transmitted; processor (some RI=1) or if any output lines have transmitted characters and can accept new characters (some TI=1).

The DIAC instruction, which reads input characters and line control information also clears the receiver indicator of the line just read. Upon issuance of DIAC AC QTY, QTY DONE will be cleared if there are no other lines with data to be read and if all transmit indicators (for all lines) are 0. If there are additional lines to be read or character completions which need be handled, QTY DONE will remain set.

The DOA AC, QTY instruction, which supplies a character for output on a selected line, also clears the transmit indicator for that line. If no new character is to be outputted, the DOB AC, QTY instruction may be used to clear the transmit indicator without sending a new character. While DOA or DOB clears the transmit indicator for a line, they will clear QTY DONE only if there are no other lines on which transmission has completed and if no receivers have assembled characters for the processor to read. The S-pulse is not microcoded as a part of an instruction.

. The QTY BUSY flag is set whenever output is occuring on any of the lines. It clears when all characters on all lines awaiting transmission have been sent.

IO INSTRUCTIONS

DIAC AC, QTY reads the following word:

0	1	2		,	8		15
R	т		line			Chara II	
Ι	Ι		IIne			Character	

- RI Receive indicator -- a character has been assembled and appears in bits 8-15, right justified.
- TI Transmit indicator -- a character previously sent to the transmitter has been accepted for transmission and a new character may be sent.
- line The line number to which the indicators apply.
- indicated line if RI is set; undefined if RI is not set.
 - DOA AC, QTY assumes the following word in an accumulator:

78 line character 012 15

- line The line number on which the character is to be transmitted and for which the transmit indicator is to be cleared. Bits 0 and 1 are ignored.
- right justified in the byte if less than 8 bits.
- DOB AC, QTY assumes the following word in an accumulator:

line - The line number (0,1,2 or 3 for a single card system) for which the transmit indicator is to be cleared. Bits 0,1, and 8 through 15 are ignored.

DIA AC,	MDM	senses the state of the Ring Indicator signal from 16 lines. AC bit 0 in the logical zero state indicates that line 0 is ringing; AC bit 15 in the logical zero state indicates that line
		15 is ringing, etc.

DIB AC, MDM senses the state of the Data Set Ready signal froml6 lines. A logical one indicates that the data set is ready.

DOA AC, MDM controls the state of the Data Terminal Ready signal to each of 16 lines. A logical zero in any bit makes the corresponding line ready.

MODEM CONTROL

)

In order to use a four-line receiver/transmitter card with Bell System 103 Type data sets (modems) or equivalent equipped for automatic answer, additional modem control circuitry is required. This circuitry is not required on lines with manual answer or for dedicated (leased) lines. The control may be provided using the type 4026 interface subassembly with one type 4027 interface for each group of four lines controlled. The 4027 interface provides control of the Data Terminal Ready (Circuit CD) and permits detection of the Ring Indicator (Circuit CE) and Data Set Ready (Circuit CC). Note that the Clear to Send signal and the Carrier Detector signal (Circuit CF) carry identical signals in normal 103 type modem operation; these are examined by the 4062 or 4063 transmitter circuitry. A maximum of four 4027 interfaces can be supplied with each 4026 interface subassembly, which is sufficient to service 16 lines. The required hardware configuration for automatic answer includes: 1) a 4063 multiplexor and a 4027 interface for each group of four or fewer lines and 2) a 4051 junction panel, two 4052A cable assemblies, and a 4026 interface subassembly for each group of 16 lines or less. The purchase order must note that the 4026 is for use as modem control with a 4063 multiplexor system.

In order to use the four-line receiver/transmitter card with Bell System 202 Type data sets (modems) or equivalent equipped for automatic answer on a two wire (half duplex) line or in a multipoint network, control circuitry in addition to that described above is required. A second type 4027 interface is required for each group of four lines so configured. Control is provided for Request to Send and detection facility is provided for Data Carrier and Clear to Send.

SECTION 4

INSTALLATION AND CABLING

CODE SELECTION

A number of transmission codes can be accommodated. Jumpers on the card are used to select line speed, level (number of data bits), and either 1, 1½, or 2 units of stop code. All models are shipped configured for 11 unit, 8 level code at 110 baud; they must be customized by the user for his particular needs. 1½ unit stop code operation is available only with 5 level code (Baudot).

The user can alter the jumper pattern to suit his needs. Select code structure level and units as follows:

			Jumpe	rs Installed
Level	Units	Example	Level	Stop
5	7 ነ	TTY 28		W17,W28
6	8		W13	W17,W29
	9		W13	W17,W18,W29
7	9	IBM 2741	W12	W16,W18,W29
	10		W12	W15,W16,W18,W29
8	10	TTY 37	W12,W13	W15,W16,W19,W29
	11	TTY 33	W12,W13	W14,W15,W16,W19,
		or 35		W29

Jumpers on the card also determine the four most significant line number address bits. In a system with multiple cards, the card physically mounted closest to the processor card must contain line number group 0 to 3. Line numbers increase as cards are installed further along the I/O bus. Cards are supplied to respond as group 0-3 when ordered individually; when supplied in a system, they are assigned to sequential groups.

Group	Jumpers Installed
0-3	W20,W21,W22,W23
4-7	W20,W21,W22
8-11	W21,W22,W23
12-15	W21,W22
16-19	W20,W21,W23
20-23	W20,W21
24-27	W21,W23
28-31	W21
32-35	W20,W22,W23
36-39	W20,W22
40-43	W22,W23
44-47	W22
48-51	W20,W23
52-55	W20
56-59	W23
60-63	(None)

The line speed is derived from a precision 76.8KC oscillator by the choice of jumpers in a frequency divider chain. Accuracy of the derived frequency is better than .6 of 1%. For frequencies other than those listed above or for more precise control of the frequency, order clock option 4064 and specify the desired baud rate. The crystal frequency will be chosen to be 128 times the baud rate.

Baud Rate	Jumpers Installed
75	W1,W2,W3,W4,W6,W7,W8
110	W2,W3,W6,W8
134.5	W2,W3,W6
150	W1,W2,W3,W4,W7,W8
300	W1,W2,W3,W4,W8
600	W1,W2,W3,W4
1200	W2,W3,W4
2400	W3,W4
4800	W4
9600	(None)

4064 W1,W2,W3,W4 (Clock Option)

In order to establish a priority order among the several cards in a system, wiring like the INTP wiring on the back panel is required. Connect pin A91 of each four-line card to pin A92 of the next successive fourline card and along the bus.

The installation and cabling scheme is considerably different between the 800/1200 and 1210/1220/820 processor, and therefore will be separated in this document.

800/1200 PROCESSORS

)

)

For systems containing only a single card (four lines), individual 9-pin connectors are usually provided on the back of the computer chassis. (See Figure 1). Order Model 4060 or 4062.

A Type 4050 or 4051 junction panel is normally used to interconnect the individual cables from a number of teletypes or data sets (modems) to the multiplexor. Requiring 1-3/4 inches of rack space, the panel contains 16 connectors (4050: 9-pin connectors for Teletype; 4051: 19-pin connectors for data sets (modems)) for attaching the devices and 1 or 2 connectors for connection to the multiplexor and optional automatic answer facility (using 4052 cables). Order Model 4061 or 4063.

In mixed systems (eg; 8 data sets and 4 local Teletypes), the data set (modem) version of the junction panel must be ordered, together with adapter cables which convert the 19-pin connectors to 9 pins for the teletypes. Refer to Example 1 for a sample configuration.

1210/1220/820

For systems requiring up to 16 lines on a 4 slot processor, and up to 32 lines on a 10 slot, the connectors are usually locatable directly on the processor using 1 or 2 4083 16-line connector assemblies. The 4063 EIA and/or 4061 TTY interfaces are used for this configuration. Refer to Example 2 for a sample configuration.

For configurations requiring more connections than allowed according to the above rules or systems where the customer wants a remote connection panel, 50-pin paddle boards are provided. Each of these 50-pin connectors have connections for all of the data leads associated with 1-4060 or 4062 board. Refer to Example 3 for a sample configuration.

MAINTENANCE

A combined diagnostic and reliability test program (tape 095-000073, listing 096-000040) is available for maintenance of a 4060 system. The reliability portion of the test is run to insure satisfactory overall system operation; the diagnostic test is run to localize failures on a board to the failing circuitry. Test plugs are normally used to replace the terminals while tests are run. If the system includes data sets, these often provide a loop-back test mode which performs the same function as the test plug.

EXAMPLE 1:

For 1200/800 type processors. See Figure 2 for diagram of this example.

A typical Nova 1200 computer based communication system with 12 lines attached to 103 Bell System data sets (modems) with automatic answer and four local teletypes.

REQUIRED:

- 1 1200/800/1230 Type Nova Line computer plus core memory.
- 1 4061 four-line asynchronous receiver/transmitter equipped for 20 ma. TTY interface.
- 3 4063 four-line asynchronous receiver/transmitter equipped for EIA type interface.
- 1 4026 Interface subassembly
- 3 4027 EIA type interfaces
- 1 4051 Data set junction panel
- 2 4052A Cable for connecting one 4026 and the 4063-4061 combination to the 4051
- 4 1020A Connector adapters

OPTIONAL:

- 12 1018A Interconnect cable for 4051 to 103 data set (modem)
- 4 4010A or 4010E 33 ASR Teletypes
- 4 1019A Extension cables for use with 4010.

EXAMPLE 2

For 1210,1220,820 processors using 4083 connector panel. (See Figure 4)

A typical computer based communication system with 12 lines attached to 103 Bell System data sets (modems) with automatic answer and four local Teletypes.

REQUIRED:

)

- 1 Any Nova-line computer plus core memory,
- 1 4061 four-line asynchornous receiver/transmitter equipped for 20 ma. TTY interface.
- 3 4063 four-line asynchronous receiver/transmitter equipped for EIA type interface.

- 4026 Interface subassembly
 4027 EIA type interfaces
 4083 Connector panel ordered as:

#4083 - 16-LINE CONNECTOR

Line #	Description			
0 1 2 3	lst 4061 - TTY Interface lst 4061 - TTY Interface lst 4061 - TTY Interface lst 4061 - TTY Interface lst 4061 - TTY Interface

12	3rd 4063/4026 EIA w/Modem Control Interface			
13 14	3rd 4063/4026 EIA w/Modem Control Interface 3rd 4063/4026 EIA w/Modem Control			
15	Interface 3rd 4063/4026 EIA w/Modem Control Interface			

OPTIONAL:

- 12 1049-0 Interconnecting cables from 4083 to Modem
- 4 1019-C Extension cables for use with 4010
- 4 4010A or 4010E 33 ASR Teletypes

EXAMPLE 3

For 1210,1220,820 processors using 50-pin paddle board connectors.

CONFIGURATION EXAMPLE

A typical computer based communication system with 12 lines attached to 103 Bell System data sets (modems) with automatic answer and four local Teletypes." No external cable is available from Data General to interface an Auto Answer Modem to 50-pin paddle boards. No internal cross wiring is done between the 4063's and the 4026/27 Modem Control. See Figure 3 for graphic presentation of this example.

REQUIRED:

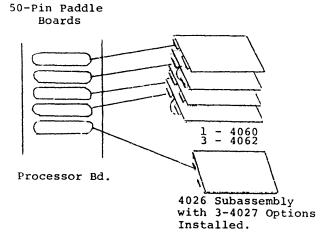

- 1 Any Nova-line computer plus core memory
- 1 4061 four-line asynchronous receiver/transmitter equipped for 20 ma. TTY interface.
- 3 4063 four-line asynchronous receiver/transmitter equipped for EIA type interface
- 1 4026 Interface subassembly
- 3 4027 EIA type interfaces

OPTIONAL:

- 4 1019B Extension cables for use with 4010
- 4 4010A or 4010E 33ASR Teletypes
- * (See Figure 4)

FIGURE 3

Typical 16 line system for 1210,1220, 820 system processors -- As given in Example 3.

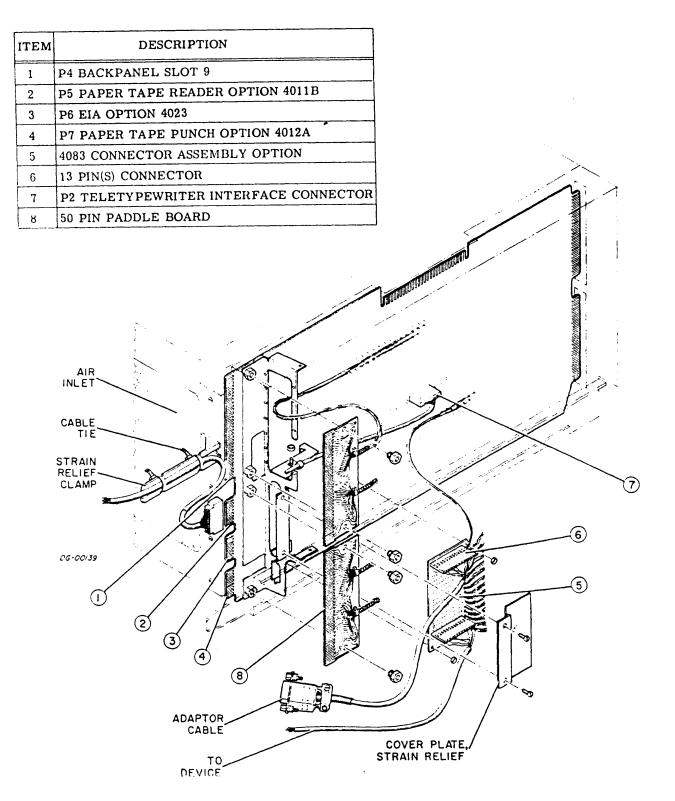

Figure 4 Sketch of the Nova 1220 & 820 Cabling Scheme. The 1210 Cabling is similiar, except it has half the capacity for connectors. Note that the 4083 Connector Panel is physically attached to the Processor.

SECTION 5

THEORY OF OPERATION

Each four-line card contains five major sections including:

- Interface to computer I/O system. a)
- b) Interface circuitry (either 20 ma. loop or EIA) to match the TTL logic circuitry to the communications lines.
- C) Clock oscillator and divider chain.
- d) Four buffered serial to parallel receivers.

)

e) Four buffered parallel to serial transmitters.

The computer I/O interface circuitry performs few functions beyond decoding I/O instructions so that one of the receivers or transmitters on the card can respond appropriately. It provides priority chain logic which functions much like INTP IN/OUT so that only one card responds to I/O instructions at any time. The clock circuitry is a straightforward oscillator and divider which provides a clock signal at eight times the baud rate.

The transmitter circuitry comprises a parallel buffer register and a shift register. When the buffer empties, a program interrupt is generated and a character is requested from the processor. When a character is outputted, it is first loaded into and held in the parallel register. At any integral number of bit times after the last stop bit of the previous character has begun, the serial register is available for loading from the parallel holding register. When loaded, a starting space is put on the line and the shift register is enabled to shift every bit time thereafter.

The end of a character is detected by examining the code pattern which was shifted into the transmitter as the character bits were outputted.

Operation of the receiver is the reverse of the transmitter. A serial bit stream is assembled in a shift register and then, fully assembled, it is loaded into a parallel holding register which, in turn, interfaces to the programmed I/O facility. The only complex part of the operation centers around synchronization of the receiver to the incoming bit stream. The line is examined for a space which, when detected, enables a divide-by-eight circuit. Should the line immediately return to the marking state, the space is ignored as extraneous noise. Should the line remain spacing for 1/2 bit time, the divide-byeight circuitry produces a clock signal in the center of each bit interval.
